# 1 Introduction

# 1.1 Purpose

This document describes the Speedway Revolution platform and high-level architecture. It is intended for embedded software developers designing custom application software to run on the Speedway Revolution Reader, xPortal and xArray Gateway products.

# 1.2 Scope

This document describes at a high level how to use the basic functionality of the Speedway Revolution Reader. Both the xPortal and xArray Gateway products embed Speedway Revolution Readers, and hence inherit all of the Reader's capabilities with regard to on-reader application development. This document also provides detailed information about the platform architecture provided by Impinj to custom application embedded software developers.

Information in this document pertains to the Octane 5.2.0 firmware.

# 1.4 Acronyms

**API:** Application Programming Interface

**CAP:** Custom Application Partition **CDR:** Configuration Default Restore

CLI: Command Line Interface CPU: Central Processing Unit

DC: Direct Current

**DE9:** 9-pin D-sub E-shell connector [1]\_\_ **DE15:** 15-pin D-sub E-shell connector<sup>1</sup>

**DHCP:** Dynamic Host Configuration Protocol

FCR: Factory Configuration Restore

FDR: Factory Default Restore

FPGA: Field Programmable Gate Array

FS: File System

FTP: File Transfer Protocol

GPIO: General Purpose Input/Output

**IP:** Internet Protocol

LED: Light Emitting Diode

LLRP: Low Level Reader Protocol

MAC: Media Access Control

MIPS: Million Instructions per Second

MTD: Memory Technology Device

NC: Not Connected

NFS: Network File System

NTP: Network Time Protocol

NVP: Name/Value Pair

PoE: Power over Ethernet

**RAM:** Random Access Memory

RF: Radio Frequency

**RFID:** Radio Frequency Identification

RP-TNC: Reverse Polarity-Threaded Neill-Concelman connector

**SDK:** Software Development Kit

SDRAM: Synchronous Dynamic Random Access Memory

**SOP:** System Operating Partition

SPP: System Persistent Partition

SSH: Secure Shell

**UHF:** Ultra-High Frequency

URI: Universal Resource Identifier (RFC 3986)

USB: Universal Serial BusLLA: Link-Local Addressing

mDNS: Multicast Domain Name System

# 2 Platform Architecture

The Speedway Revolution R220 and R420 Readers are fixed UHF Gen2 RFID tag Readers that provide network connectivity between tag data and enterprise system software. The Impinj xPortal and xArray Gateways integrate a reader with antenna arrays for portal and wide-area monitoring applications respectively.

This Embedded Developer's Guide provides instructions on how to configure the Speedway Revolution platform application program interface, called the Custom Application Partition (CAP). It assumes the embedded software developer is familiar with appropriate networking facilities, the EPCglobal Gen2 specification, and general principles of RFID system management.

# 2.1 Speedway Revolution Reader Enclosure

Refer to the figures below for pictures of the Speedway Revolution Reader enclosure with major ports, connectors, and status indicators clearly labeled. Figure 2.1 depicts the hardware (network, power, Ethernet, etc.) ports, and Figure 2.2 depicts the antenna ports and status LEDs.

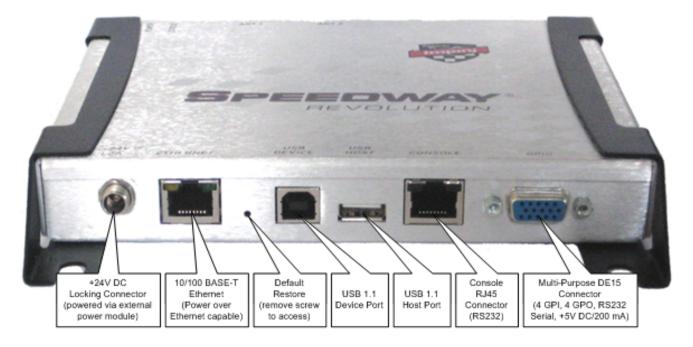

Figure 2.1 Speedway Revolution Hardware Connections

The Speedway Revolution Reader is equipped with the following hardware connectors:

• Locking 24V DC power supply connector (labeled +24V DC 1.0A)

- RJ45 Power-over-Ethernet capable Ethernet jack (labeled ETHERNET)
- USB 1.1 Type B port (labeled USB DEVICE)
- USB 1.1 Type A port (labeled USB HOST)
- RJ45 RS232 Serial Console connector (labeled CONSOLE)
- Female DE15 connector with user I/O capability. Secondary RS232 serial, four optoisolated inputs, four optoisolated outputs. See section 2.5 for the details and pin out of the Speedway Revolution GPIO.

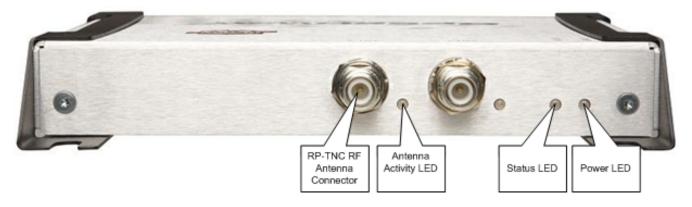

Figure 2.2 Speedway Revolution Antenna Connections

The Speedway Revolution Reader is equipped with the following antenna connectors and LEDs:

- Two (R220, pictured) or four (R420) female RP-TNC antenna connectors (labeled ANT1-ANTn).
- Two (R220, pictured) or four (R420) antenna activity LEDs. For more information, see section 2.6.
- One status and one power LED. For more information, see section 2.6.

# 2.2 xPortal Gateway Enclosure

The antennas are connected to the internal antennas and therefore aren't accessible.

# 2.3 xArray Gateway Enclosure

Figure 2.3 shows the xArray Gateway enclosures connections.

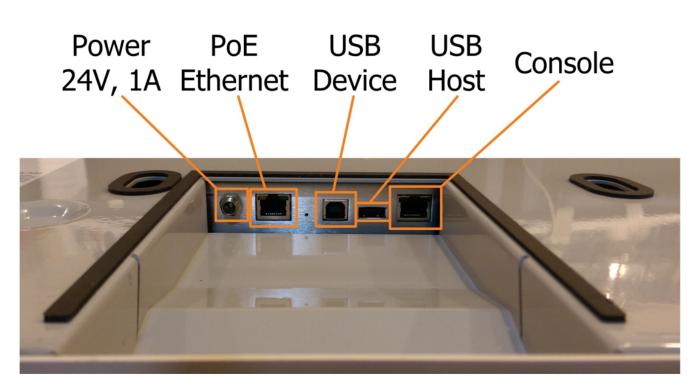

Figure 2.3 xArray Hardware Connections

The antennas are connected to the internal antennas and therefore aren't accessible. In addition, the embedded reader's female DE15 I/O connector is used internally and therefore isn't available for on-reader applications.

# 2.4 Speedway Revolution Power Supply

Speedway Revolution Readers can be powered by either an external 24V power supply, or via Power over Ethernet (PoE). Only one power supply is active at a time, and the default power supply is via the 24V external supply when connected. To use PoE, the 24V external supply must be disconnected, and the Ethernet port connected to a cable that is attached to either a PoE injector or a PoE-enabled network switch. A change in active power supply, such as pulling the 24V external supply while a PoE-enabled Ethernet cable is attached, will result in a Reader reset.

# 2.5 Speedway Revolution GPIO

Speedway Revolution Readers provide the user with a multipurpose I/O port that contains a RS232 serial port, four optoisolated inputs, four optoisolated outputs, and a +5V supply. These features are accessed through a DE15 connector mounted on the back of the Reader.

The four optoisolated inputs have a range of 0-30V. The Reader will treat an input of 0-0.8V as logic 0, and an input of 3-30V as logic 1. The Reader has a per-input debounce interval that is configurable via LLRP. For more information, see the **Octane LLRP** document. This value dictates the minimum pulse width of an input. Impinj recommends that external devices guarantee a minimum pulse width of at least 100 milliseconds.

Four optoisolated outputs are also provided. An external power supply must be connected between V+ and V- for the GPIO outputs to function. The maximum voltage for this supply is 30V. When the user configures a selected GPIO output via LLRP to output logic 0, an isolated FET switch in the Reader effectively shorts that output to V-, with a current sink capability of up to 200mA. When the user configures a selected GPIO output to logic 1, the selected output is pulled to V+ through a 10K resistor. If GPIO isolation is not required, the Reader provides a +5V supply and a ground pin on the DE15 that can be connected to V+ and V-.

See Figure 2.4 and Table 2.1 for details regarding the pin-out of the DE15.

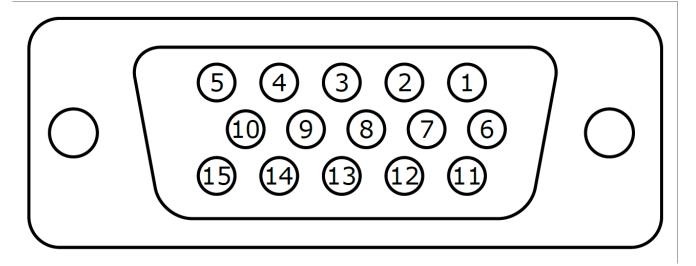

Figure 2.4 DE15 Female Connector

Table 2.1 provides the signal name and a description for each DE15 Connector pin.

Table 2.1 DE15 Connector Pin-Out

Pin	Signal Name	Description
1	USER_5V	+5V supply
2	$RS232\_RXD$	RS232 serial receive
3	$RS232\_TXD$	RS232 serial transmit
4	DB_DEFAULT_RST	Factory default restore (currently unused)
5	VPLUS	Positive supply for optoisolated GPO
6	VMINUS	Negative supply for optoisolated GPO
7	GND	Ground

Pin	Signal Name	Description
8	USEROUT_0	General purpose output 0 (LLRP 1)
9	USEROUT_1	General purpose output 1 (LLRP 2)
10	${\tt USEROUT\_2}$	General purpose output 2 (LLRP 3)
11	$USEROUT\_3$	General purpose output 3 (LLRP 4)
12	USERIN_0	General purpose input 0 (LLRP 1)
13	USERIN_1	General purpose input 1 (LLRP 2)
14	$USERIN\_2$	General purpose input 2 (LLRP 3)
15	USERIN_3	General purpose input 3 (LLRP 4)

When the Speedway Revolution Reader is used with Speedway Reader Antenna Hub accessories, the GPIO port is used to interface to the GPIO Adaptor Kit. In this configuration, the GPIOs and the serial port are no longer available for embedded applications to use.

# 2.6 Speedway Revolution Reader LEDs

The Speedway Revolution Reader has several LEDs to indicate Reader operational status. The three primary LED categories are power, Reader status, and antenna status. Each LED has its own blink patterns to convey status to the user. Table 2.2 documents the defined patterns for the Power LED. Table 2.3 documents the defined patterns for the Reader Status LED. Table 2.4 documents the defined patters for the Antenna Status LEDs.

Table 2.2 Power LED Patterns

LED State	Reader State
Solid RED (after power-on or reset)	Power applied, attempting to start boot code
OFF	Default Restore button pressed
One short RED blink	Configuration Default Restore detected
	For more information, see section 3.1.1.
Two short RED blinks	Factory Default Restore detected
	For more information, see section 3.1.1.
Blinking RED (4 Hz)	Unable to boot (see console for details)
Solid GREEN	Done booting, starting application image
Blinking ORANGE (1Hz)	USB flash drive upgrade in progress
Blinking RED (2 Hz)	USB flash drive upgrade failure

Table 2.3 Reader Status LED Patterns

LED State	Reader State
OFF	Application image booting, RFID not available
Alternating RED	Application image booting, RFID not available, File system operation
and GREEN	in progress (after upgrade)
Solid GREEN	Application image booted, RFID available
Two short GREEN	LLRP connection active
blinks	
One short GREEN	LLRP active, but no LLRP connection
blink	
Blinking ORANGE	Inventory active, blinking rate increases with an increased number of
	tags in the Reader FOV

Table 2.4 Antenna Status LED Patterns

LED State	Reader State
OFF	Antenna inactive
Solid GREEN	Antenna actively transmitting

The Speedway Revolution Reader's antenna, power and status LEDs are not visible in the xPortal and xArray Gateway products.

# 2.7 xArray Gateway LEDs

The xArray Gateway has four LEDs to indicate operational status, their position is shown in Figure 2.5. The Power LED is ON (GREEN) when power is applied.

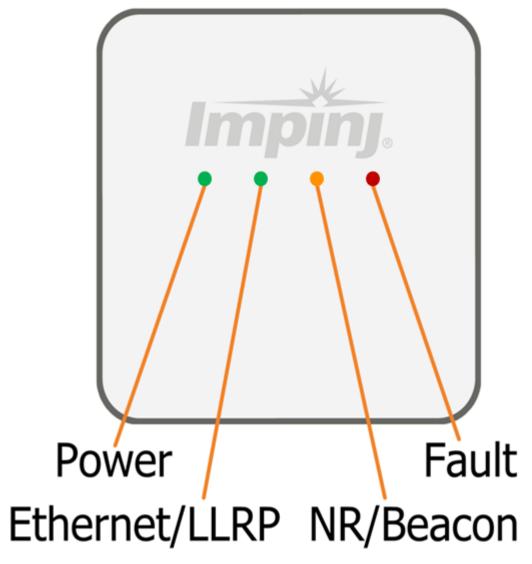

Figure 2.5 xArray Status LEDs

Each LED has its own blink patterns to convey status to the user. Table 2.5 documents the defined patterns for the xArray Ethernet/LLRP LED. Table 2.6 documents the defined patterns for the xArray NR/Beacon LED. Table 2.7 documents the defined patters for the xArray Fault LED.

Table 2.5 xArray Ethernet/LLRP LED

LED State	xArray State
OFF Blinking (GREEN)	During startup Ready for an LLRP host connection
Solid (GREEN)	LLRP host connected

Table 2.6 xArray NR/Beacon LED

LED State	xArray State
Blink (ORANGE)	Briefly during startup
OFF	(Default)
ON (ORANGE)	When turned ON by LLRP command

Table 2.7 xArray Fault LED

LED State	xArray State
Blink (RED)	Briefly during startup
OFF	Normal (no faults)
ON (RED)	Fault condition occurred

# 2.8 Speedway Revolution Console Port

The Speedway Revolution console port uses RS232 serial over a RJ45 cable. Because most computers do not have a RJ45 COM port (DE9 COM ports are typical), a RJ45-to-DE9 converter cable will likely be required to connect to the Reader's console port. The Speedway Revolution RJ45 port uses a Cisco-compatible pin out and these cables are readily available from many third-party vendors. However, in the event that such a cable is unavailable and a cable must be built by hand, Table 2.8 documents the pin mapping from a female DE9 connector to a male RJ45 connector. Note that the table below is complete in terms of the pin-to-pin mapping, but only RJ45 pins 3 (RD), 4 (GND), and 6 (TD) are required for proper operation. The remaining pins are not utilized by the Reader and are left unconnected.

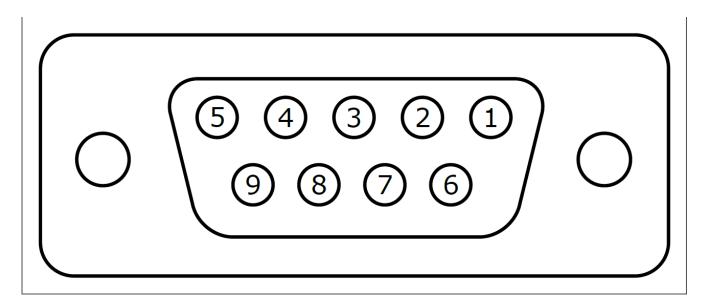

Figure 2.6 DE9 Female Connector

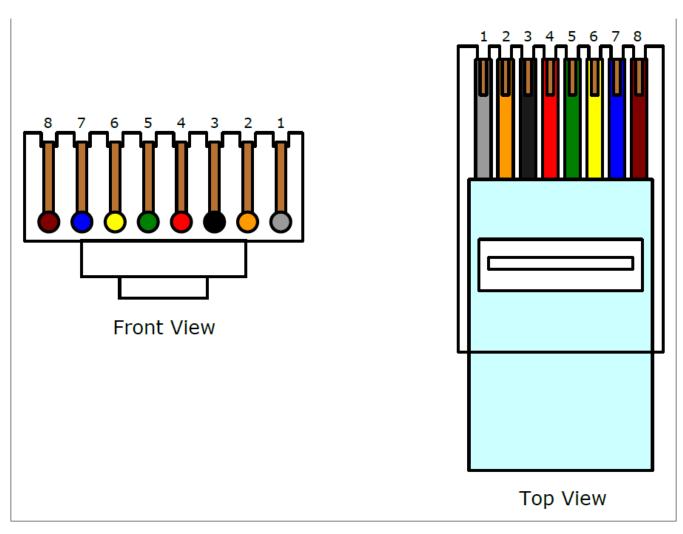

Figure 2.7 RJ45 Male Connector

Table 2.8 documents the pin mapping from a female DE9 connector to a male RJ45 connector.

Table 2.8 RS232 DE9-to-RJ45 Pin Mapping

RS232 Signal	DE9 Pin	RJ45 Pin	Color (typ.)
Data Carrier Detect	1	NC	N/A
Receive Data	2	3	Black
Transmit Data	3	6	Yellow
Data Terminal Ready	4	7	Blue
Signal Ground	5	4	Red
Data Set Ready	6	2	Orange
Request to Send	7	8	Brown
Clear to Send	8	1	Gray

RS232 Signal	DE9 Pin	RJ45 Pin	Color (typ.)
Ring Indicator	9	NC	N/A

# 2.9 Platform System Overview

The Speedway Revolution Reader is a single processor system, with the control platform based on an Atmel AT91SAM series controller. For a hardware block diagram, see Figure 2.8. Air-protocol and time-critical functions are implemented within an FPGA. This architecture arrangement leaves anywhere from 50% to 90% of the control CPU MIPS (depending on the inventory load) available for custom application software. The control microprocessor also has NAND flash memory and SDRAM available for firmware and data storage. See sections 2.10 and 2.11 for flash and SDRAM allocation schemes, respectively, to determine how much is available for custom application development.

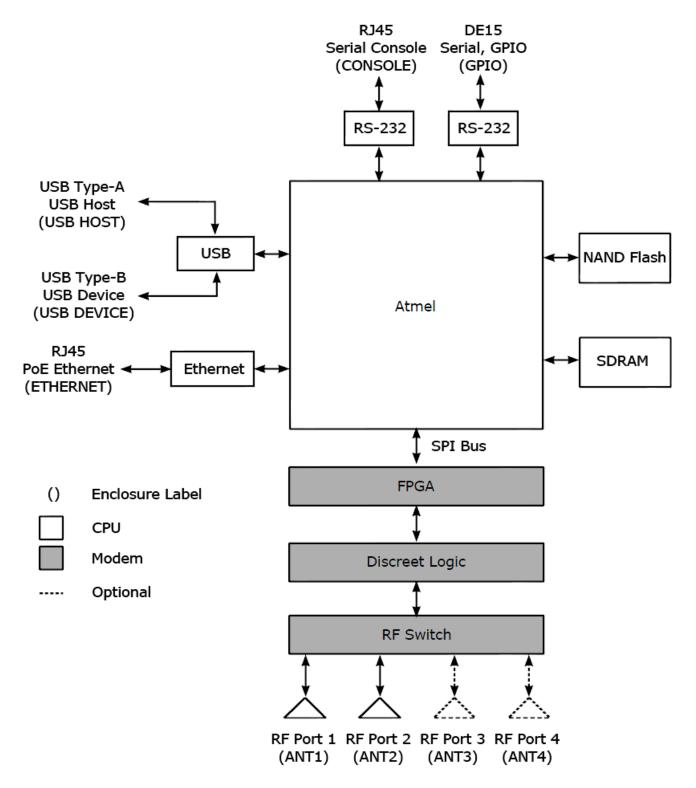

Figure 2.8 Speedway Revolution Hardware Block Design

The Speedway Revolution Reader's CPU hardware subsystem was updated in later revisions of the hardware. The PCBA version can be used to determine which components are present.

Table 2.9 CPU Hardware Update Summary

H/W Component	PCBA v4.xx (and lower)	PCBA v5.xx (and higher)
Micro-controller, clk	AT91SAM9260, 200Mhz	AT91SAM9G20, 400Mhz
NAND Flash	128 Mbytes	256 Mbytes
SDRAM	64 Mbytes	128 Mbytes (xArray) 64 Mbytes
		(others)

For the purposes of this document, SDRAM and RAM are synonymous.

# 2.10 Flash Organization

The Speedway Revolution flash device is logically partitioned as shown in Figure 2.9. The dual image architecture supports a minimal downtime during firmware upgrades and provides for maximum robustness for upgrade failure scenarios (power outage, etc.). The firmware upgrade agent downloads the secondary image into the upgrade file system in the background while the primary image runs. The availability of the second image supports a firmware fallback if the latest upgrade does not work properly or if the primary image is corrupted. This dual image partitioning also supports a return to factory default firmware.

Figure 2.9 Speedway Revolution Flash Organization

Within each firmware image are individual JFFS2 formatted partitions that are used to logically organize the system software. Each image is partitioned as shown in Figure 2.10. Nominal sizes are given, but the actual sizes reported by the Reader include an allowance for bad flash blocks. The details regarding each partition are in the sections that follow. The Linux OS may report the file systems being larger than specified here, this is to account for redundancy in the NAND flash memory.

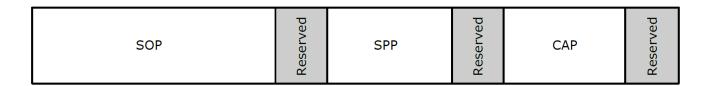

Figure 2.10 Speedway Revolution Image Organization

The Speedway Revolution Reader's NAND Flash Partition sizes were expanded in later revisions of the hardware. The PCBA verson can be used to determine which components are present.

Table 2.10 Speedway Revolution Image Partition Sizes

Image Partition Name	PCBA v4.xx (and lower)	PCBA v5.xx (and higher)
Octane Firmware Partition (SOP)	16 Mbytes	28 Mbytes
System Persistent Partition (SPP)	8 Mbytes	16 Mbytes
Custom App Partition (CAP)	8 Mbytes	32 bytes

# 2.10.1 System Operating Partition (SOP)

This is the primary system partition of the Speedway Revolution Reader. Embedded developers can't modify the contents of this partition. This partition is mounted read-only at / (root). The primary contents of the SOP are:

- Linux 2.6.39.4 kernel
- FPGA firmware
- RFID management software
- Reader management (RShell for more information, see RShell Reference Manual)
- Logging management software
- Firmware upgrade control
- System watchdog software
- Factory default data

## 2.10.2 System Persistent Partition (SPP)

This is the persistent partition of the Speedway Revolution Reader. Embedded developers can't modify the contents of this partition. Files in this partition are automatically generated and

maintained by the software running on the Reader. Manual manipulation of these files will result in undefined Reader behavior. This partition is mounted read-write at /mnt/spp. The primary contents of the SPP are:

- Reader configuration (e.g. network settings, LLRP configuration, log settings)
- Reader logs (both application logs and error logs)
- Reader crash information (used internally by Impinj for debugging)

## 2.10.3 Custom Application Partition (CAP)

This is the custom application partition of the Reader. Embedded developers are free to make use of this partition as required by their application (subject to the constraints within). The use of this partition is the primary focus of this document. This partition might or might not be present on a Reader, depending on whether a CAP partition was included in the upgrade file. If a CAP is present on the Reader, this partition is mounted read-write at /cust. If a CAP is not present on the Reader, the /cust directory will be mounted read-only and will be empty. The primary contents of the CAP are typically:

- Custom application software
- Extra libraries or tools required by the custom application
- Configuration files used by the custom application
- Custom application logs

Note that, while this partition is mounted read-write, custom application developers should limit the use of this file system for dynamic data storage to avoid excessive wear of the flash memory. Wherever frequent modifications are required within a file system, we recommend that custom application developers use the RAM file system. For more information about the RAM file system, see section 2.11.3.

## 2.10.4 Upgrade File System

The upgrade file system is not included in a firmware image and thus is not considered a partition like those discused in previous sections. Instead, the upgrade file system is used by the active image to perform firmware upgrades, regardless of which image is active. During an upgrade, the firmware upgrade application downloads the upgrade image to this file system. In this way the image file doesn't have to be stored in RAM, which increases the RAM available for Speedway and custom applications. However, this means that the upgrade file system must always be empty or the upgrade process will fail. Therefore, embedded developers are prohibited from using this space,

and anything placed here could be deleted at any time. This file system is mounted read-write at /mnt/ufs.

Table 2.11 shows Upgrade File System sizes. Nominal sizes are given; the actual sizes reported by the Reader include an allowance for bad flash blocks.

Table 2.10 Speedway Revolution Upgrade File System Size

Image Partition Name	PCBA v4.xx (and lower)	PCBA v5.xx (and higher)
Upgrade File System (UFS)	32 Mbytes	63 Mbytes

#### 2.11 RAM Allocation

The Speedway Revolution RAM is used for several purposes during runtime. While the Linux kernel manages the allocation of the available RAM, the total RAM available is limited. Custom application developers should be aware of the restrictions imposed by a finite amount of RAM and zero swap space. The RAM on the Reader is shared between the Linux OS, Reader applications, custom applications, and the RAM file system.

#### 2.11.1 Linux OS

It is impossible to accurately measure the total RAM required by the Linux kernel and its associated drivers. However, certain kernel file systems and drivers have well-known requirements. As of Octane 4.6, the Linux kernel requires approximately 10 Mbytes of RAM.

#### 2.11.2 Reader Applications

The Reader applications stored in the SOP, as described in section 2.10.1, control every aspect of the Speedway Revolution Reader. Each of these applications is critical to the Reader operation, whether it is RFID operations, firmware upgrades, system management, or log control, and each application requires RAM.

#### 2.11.3 RAM File System

The RAM file system is available as temporary storage for dynamic data. This is the recommended file system to use for data that is volatile, requires fast access, or doesn't need to persist across Reader resets. Embedded software developers should use this file system whenever possible in

place of the CAP (discussed in section 2.10.3) to avoid flash wear. This file system is mounted read-write at /tmp and consumes 1 Mbyte of RAM.

The larger RAM file system can be mounted as follows:

/bin/mount tmpfs /var/bigram -t tmpfs -o size=8M

## 2.11.4 Custom Applications

In theory, custom applications can use the remaining RAM at their discretion. However, it is imperative that embedded developers understand the dynamic memory requirements of a real-time system. While the used memory presented in this section is accurate, system activity can cause fluctuations in the required memory (such as during a firmware upgrade). To ensure proper system operation, Impinj recommends that custom applications consume no more than 8 Mbytes of RAM. Failure to do so may result in abnormal system behavior and possible system reset as the available memory approaches zero.

## 2.11.5 RAM Allocation by Product

Table 2.11 Octane 5.2 RAM Allocation

Product	Used by Octane	Available	
Speedway Revolution Reader	~32 Mbytes	16 Mbytes	
xPortal Gateway	$\sim 32 \text{ Mbytes}$	16 Mbytes	
xArray Gateway	~48 Mbytes	64 Mbytes	

Note that Speedway Revolution Readers that are embedded in xArray Gateways have 128 Mbytes of SDRAM.

# 2.12 Linux File System 2.7

During the boot process, the mounter application determines which of the two images is active and mounts the appropriate file systems on the flash MTD devices, as described in section 3.2.1. Therefore, custom applications don't need to concern themselves with the dual image design. The standard Linux file system is always guaranteed to map to the correct image. Figure 2.11 depicts the Speedway Revolution file system and how each directory is mapped into the associated memory devices.

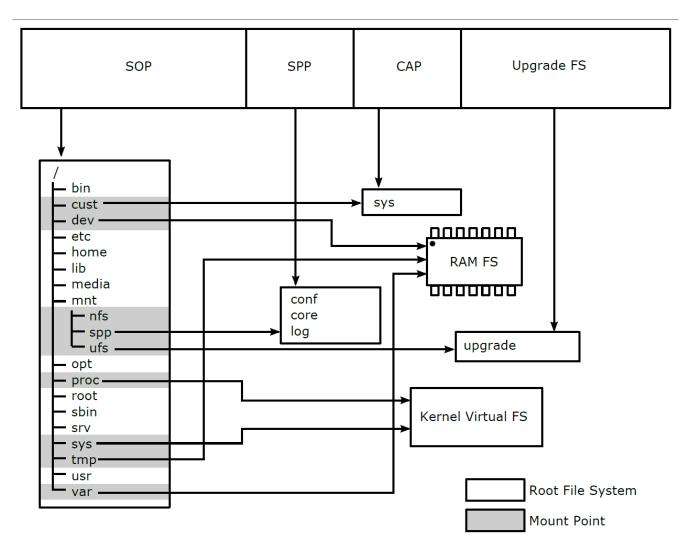

Figure 2.11 Speedway Revolution File System Layout

# 2.13 USB HID Keyboard Emulation

It is possible for your on-Reader application to send data through USB to a PC or other computer. This section describes how to use the hidkey program which provides an emulation of a USB HID (Human Interface Device) keyboard. To the PC, the Speedway Revolution RFID Reader appears to be a keyboard with somebody typing on it.

### 2.13.1 Requires On-Reader Application

To take advantage of the USB device interface, an on-Reader application is necessary, which must be cross-compiled for the target. The USB functionality is only accessible to Linux OS, so OSShell access is required to develop such an application. An example of an on-Reader application is shown in Figure 2.12.

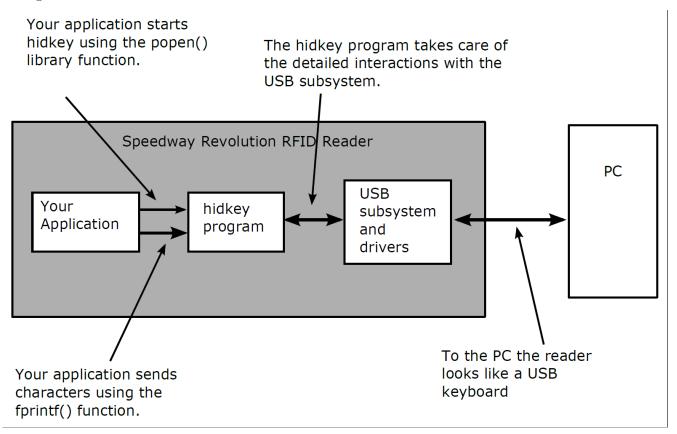

Figure 2.12 Speedway Revolution On-Reader Application

#### 2.13.2 USB Cabling

Of course, an **A-B** USB cable is necessary to connect the Reader (device) to the host (e.g. a PC). Connection to the host will almost certainly be via one or more USB hubs. The host and any hubs should be USB 2.0-compliant.

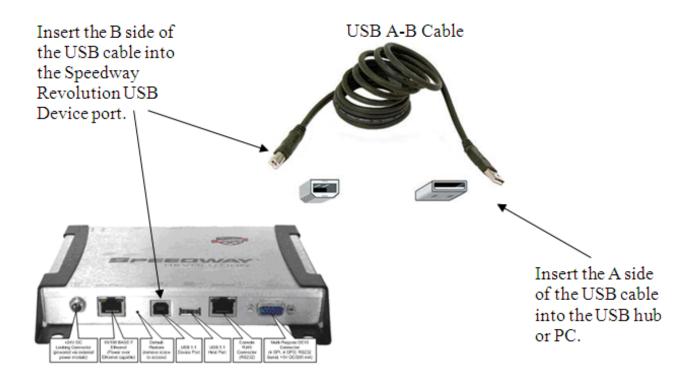

Figure 2.13 USB Cabling

#### 2.13.3 USB Presence

Based on the behavior of other USB devices, when the Reader is initially attached to the host, you would expect the host to identify the Reader. This is not the case. An on-Reader application must start the USB HID Keyboard Emulation utility before any USB activity can start. The Reader can automatically start the application each time it boots, in which case the Reader will respond as a USB device, either when attached or at power-up while still attached.

## 2.13.4 Keyboard Emulation Program (hidkey)

The USB HID Keyboard Emulation utility is an executable program named **hidkey**, which is included in the Speedway Revolution's read-only System OS Partition (SOP) at the following path:

/opt/ys/usb/hidkey

When **help** is passed as a command line option, it shows a summary of its use and command line options.

```
root@SpeedwayR-00-00-00:~# /opt/ys/usb/hidkey help

USB HID Keyboard Emulation Driver

Version: 000.000.010400.009_126_835_2102

Usage: /opt/ys/usb/hidkey [Options]

Options:

ReportInterval=<N> (default is 10ms)

KeyDelay=<K>,<D>[:<K>,<D>[...]] (upto 10 pairs)

SerialNum=Device|Random (default is Device)

SysLog=Emerg|Alert|Crit|Error|Warning|Notice|Info|Debug

DbgLvl=Emerg|Alert|Crit|Error|Warning|Notice|Info|Debug|Debug1|Debug2

Notes: #

Intervals and <D>elays are in mS, <K>eys are ASCII codes

Default SysLog is Error, default DbgLvl is Emerg

root@SpeedwayR-00-00-00:~
```

Because piping commands is well supported by the Bash shell, we can start with a shell-based example, as described in this procedure.

- 1. In order to proceed, you need to start an application on the Windows PC host that accepts keyboard input, such as an editor (e.g. Notepad) or Spreadsheet (e.g. Excel).
- 2. Now the Reader can be connected to the PC. Nothing will happen until the **hidkey** executable is started. Then the Reader will behave like a USB device and begin to enumerate. From OSShell, type the following:

```
# echo "RFID That Just Works!" | /opt/ys/usb/hidkey
```

- 3. Before enumeration completes, keyboard input must be directed to the Windows application.
- 4. If this is the first time the driver is used, pop-ups that identify the device will flash up from the Windows system tray's USB icon.
- 5. After a short pause (approx. 20 seconds), the echoed string should appear in the application on the host. This pause is inserted by **hidkey** to allow enumeration to complete.

## 2.13.5 Disconnected Operation

If the Reader becomes disconnected, the **hidkey** program will continue to consume and discard new data. Because there is no pre-defined delimiter that groups reports, a partial report might be sent as a consequence of a disconnection or re-connection. It is expected that applications can be started and re-started while there is no report activity.

When you start the **hidkey** program, if a USB connection is not present, **hidkey** will discard all input data until a connection is established and enumeration completes.

## 2.13.6 Example USB HID Application

Here is an example of how the **hidkey** program can be used.

```
* Application Example
************************************
* Outline:
* An example application that opens the USB HID Keyboard Emulation program
* (hidkey) in a non-blocking (by default) mode.
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <string.h>
#include <fcntl.h>
#include <errno.h>
#define ARRAYSIZE(a) sizeof(a)/sizeof(a[0])
#define name "MyApp"
int main(void)
 int cntr:
 FILE * pipe_fp;
```

```
int ret;
int pipe fd;
int c;
/* RFID report like test data */
char *strings[] = {
  "2009-09-03T00:12:39.705135\tEPC96\t76636575773F6B493FD7A981\n",
  "2009-09-04T00:12:40.124143\tEPC96\t76636575773F6B493FD7C74B\n",
  "2009-09-06T00:12:40.635294\tEPC96\t76636575773F6B4934B472A9\n"
};
/* Open the application with a pipe to its stdin */
fprintf(stderr, "%s: Opening pipe\n", name);
if (NULL == (pipe_fp = popen("/opt/ys/usb/hidkey", "w")))
  perror("popen");
  exit(1);
/* Get the file descriptor (from the file pointer) */
if (-1 == (pipe fd = fileno(pipe fp)))
{
  perror("fileno");
  exit(1);
fprintf(stderr, "%s: Got file descriptor (%d)\n", name, pipe fd);
/* Limit the pipe's buffer size to a (minimal) fixed size */
/* - this stops addional buffering being allocated */
setbuf(pipe fp, NULL);
/* Wait for enumeration to complete, otherwise driver discards */
sleep(20);
/* Use fputs() */
for(cntr=0; cntr<ARRAYSIZE(strings); cntr++)
{
```

```
ret = fputs(strings[cntr], pipe_fp);
   if(EOF == ret)
    /* Did the write fail because the device is backed-up? */
    if(errno!= EWOULDBLOCK)
      perror("fputs");
      exit(1);
/* Flush the pipe (won't necessarily empty it) */
fflush(pipe_fp);
/* Close stream opened by popen. */
/* - waits for and returns termination status */
fprintf(stderr, "%s: Closing pipe ...", name);
if(-1 == (ret = pclose(pipe fp)))
  perror("pclose");
fprintf(stderr, "%s: Closed. Exiting.\n", name);
return 0;
```

Figure 2.14 Example USB HID Application

## 2.13.7 Supported Characters

}

During normal operation, the hidkey program converts ASCII characters into keyboard scan codes. When an ASCII character doesn't obviously map to a keyboard scan code, it is mapped to a substitute character, a "\_\_", rather than raising an error or warning.

#### 2.13.8 Performance

During testing, it became clear that sending characters at the fastest rates (smallest polling intervals) can overflow input buffering on some slower host applications. Specifically, MS Excel would garble characters when this situation occurred. No such issues were observed when the host application was a text editor. This is likely a function of the host's performance, the host's CPU load and the host application, so it is difficult to provide any guidance.

#### 2.14 USB Flash Drive AutoRun

Speedway Revolution allows a firmware upgrade from a USB flash drive. When a USB flash drive is inserted into the Reader's USB slot, a program, informally referred to as **AutoRun**, is automatically invoked that checks for the presence of firmware upgrade files. The AutoRun program also checks to see whether an application-specific program is configured, so that the application can check for files on the USB flash drive.

## 2.14.1 USB Flash Drive Preparation

The USB flash drive program **AutoRun** works with VFAT USB flash drives. MAC and Linux (ext2 or ext3) formatted drives are not supported. Some very old flash drives support an older version of FAT with 8-character file names (with 3 character extensions); these drives are not supported. Use Windows XP or Windows Vista to manage files and directories on the flash drive, because this ensures compatibility with VFAT.

On the flash drive, create a directory X:\YourCompany\YourProduct. For example, Impinj uses \impinj\revolution to contain firmware upgrade files. It's best to use only alphanumeric characters and no spaces for file and directory names.

Remember that, on Windows, the path name separator is a backslash  $(\)$ , while on the Reader the path name separator is a forward slash.

#### 2.14.2 HardwareEvents Stanza in Reader.conf

The following stanza and parameter have been added to the /cust/sys/reader.conf file on the CAP to allow a CAP developer to indicate which command line to execute on a Mass Storage event.

[HardwareEvents]
OnMassStorageEvent=/cust/bin/mass\\_storage\\_event

This callback is executed with two parameters, the action and the path to the mounted directory. The action is either **add** or **remove**. The mounted directory is the path where the root of the USB flash drive appears. For example:

```
/cust/bin/mass\_storage\_event add /mnt/usbfs/usbsda1
```

## 2.14.3 Example Storage Event Handler

Here is an example of how the hidkey program can be used.

```
#!/bin/bash
if [ $# -ne 2 ]
then
  logger Invalid argument count
  exit 1
fi
ACTION="$1"
PREFIX="$2"
if [ "ACTION" == "add" ]
  if [ -f $PREFIX/company/product/config_file ]
  then
    cp $PREFIX/company/product/config_file /cust/config/config_file
    logger /cust/config/config file updated
  fi
elif [ "$ACTION" == "remove" ]
then
  # The USB flash drive was removed, nothing to do
else
  logger Invalid action
fi
```

Figure 2.15 Storage Event Handler

# 3 Platform Boot Process

The Speedway Revolution boot process is a multi-stage procedure that transitions the Atmel from its internal IROM ultimately to the Linux OS. Figure 3.1 depicts this process in detail. The initial stages of this procedure are outside the scope of this document. However, the Bootloader and the Linux OS are relevant to embedded developers and will be covered in the sections that follow.

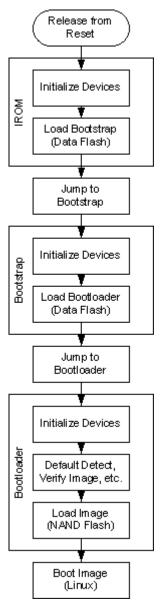

Figure 3.1 Speedway Revolution Boot Procedure

#### 3.1 Bootloader

The Speedway Revolution Bootloader, U-Boot (Universal Bootloader) is open source software. U-Boot performs processor and hardware initialization, detects factory default restore, and performs firmware image validation, invoking the newest valid image. U-Boot is not intended for direct control by a user in the field, and Impinj does not provide direct support for U-Boot.

## 3.1.1 Default Restore

There are two types of default restore, Factory Default Restore (FDR), and Configuration Default Restore (CDR). The purpose of these default restore options is to allow the end user to reset the Reader to a known state. The difference between the two restores is summarized in Table 3.1.

Table 3.1 Factory Configuration and Default Restore

	Manufacturing Data	SPP	CAP
Configuration Default Restore	Unaffected	Restored to defaults	Notified
Factory Default Restore	Unaffected	Restored to defaults	Removed

Because there is only one default restore button, as shown in Figure 2.1, the two different restore types are invoked by pressing the default restore button when the power on for different durations. As an aid, the Power LED is used to provide feedback for the duration of the button press. Table 3.2 provides the different durations required to achieve the two different default restore options. For more information about the Power LED status patterns, see section 2.6.

Table 3.2 Default Restore Button and LED Behavior

	Default Restore Button	Power LED
Configuration Default Restore	Press for 3 seconds	OFF, 3 seconds, blink RED
Factory Default Restore	Press for 10 seconds	OFF, 3 seconds, blink RED, 7 seconds, blink RED twice

## 3.1.2 Image Selection

The bootloader determines which of the two application images are valid, and which of the two is the latest. The selected image is automatically booted. If neither image is valid, the bootloader displays an error message on the console, and the Power LED blinks red indefinitely (see Table 2.2 for more information about the Power LED status). The watchdog remains enabled in this scenario, and the bootloader simply waits for the watchdog reset. See Figure 3.2 for a depiction of this process.

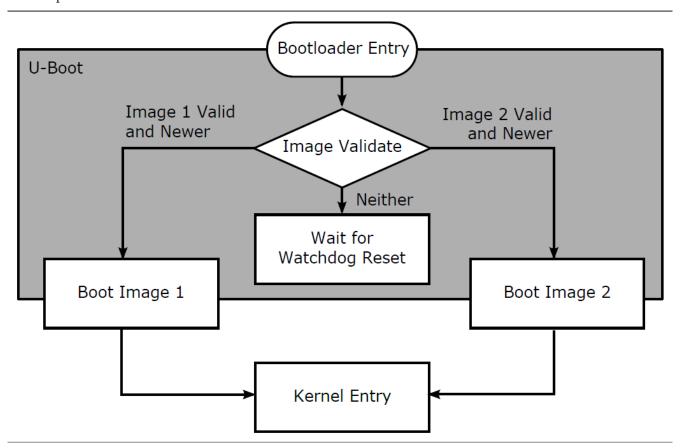

Figure 3.2 Image Selection and Boot

# 3.2 Operating System

After the bootloader has determined the appropriate image to boot, the root file system from the SOP of that image is mounted, and the Linux operating system is started. One of the first applications to start is **mounter**, which handles the upgrade scenarios.

After **mounter** has completed, the run-time Reader applications are started, including any custom applications that have been loaded.

#### 3.2.1 Mounter

Mounter is the application that is responsible for completing upgrades after the new image has been booted. Mounter has three primary responsibilities:

- Perform CDR and FDR operations
- Copy partitions not included in the upgrade image from the old image to the new image.
- Notify any CAP applications of CDR and upgrade operations

## Configuration Default Restore and Factory Default Restore

If the bootloader detects that either a configuration default restore or a factory default restore has been requested, it conveys this information via image metadata that is outside the scope of this document. After **mounter** recognizes that either a CDR or FDR has been requested, it is responsible for taking the appropriate actions.

For an FDR, **mounter** will erase the SPP and the CAP partitions, which results in a Reader with a default configuration and no custom applications.

For a CDR, **mounter** will erase the SPP, and notify the CAP of the CDR operation via the custom application's startup script. For more information about this process, see **CAP Notification** later in this section.

## Partition Copy

Upgrade image files can contain different combinations of the CAP and SOP partitions. Based on the content of the upgrade image file, certain partitions might need to be copied from the previously active image to the new image in order for the upgrade to complete. Table 3.3 documents the allowable image file partition combinations, and lists the actions that the mounter application will take in each scenario.

Note that SOP images are maintained and released by Impinj. Embedded developers will receive these partitions from Impinj and can then choose to include them with their CAP partition if desired.

The SPP partition cannot be upgraded and thus is never included in an upgrade image.

Table 3.3 Mounter Operations Based on Upgrade Image Content

CAP	SOP	Mounter Operation
X		Copy SOP/SPP
	X	Copy CAP/SPP
X	X	Copy SPP

#### **CAP Notification**

During a firmware upgrade or a configuration default restore, the **mounter** application notifies any custom applications of the operation so that the application can take appropriate action. This notification is performed by invoking an executable (the upgrade application) within the CAP partition called:

```
/cust/cust_app_upgrade
```

This application is optional and is only required if the custom application wants to receive notifications of upgrade or default restore events.

On the first boot after a configuration default restore has been performed, the upgrade application is called as:

```
/cust/cust_app_upgrade cdr
```

This notifies the custom application that the Reader has been restored to its default configuration. The custom application should then likewise restore any configuration as deemed necessary.

On the first boot after a firmware upgrade (assuming a CAP exists on the secondary image), the upgrade application is called as:

```
/cust/cust app upgrade upg <cust dir> <old cust dir>
```

This notifies the custom application on the primary image that an upgrade has been performed and that a previous version of the CAP image exists. The argument <cust\_dir> represents the new CAP root directory (in this case, typically /cust), and <old\_cust\_dir> represents the previous CAP root directory.

The upgrade application can then temporarily access the previous image in read-only mode, and can copy any configuration or persistent files to the new partition prior to starting up the custom application.

In addition to the command line arguments, several environment variables are made available to the upgrade application so that it can infer context. Table 3.4 documents the environment variables that are exported to the upgrade application. Note that, in instances where a partition does not exist, such as when there is no secondary SOP or CAP installed on the Reader, the environment variables are not defined.

## Table 3.4 Upgrade Application Environment Variables

Variable Name	Description	Example
primary_sop_vsn	Current SOP version	5.2.0.240
primary_cap_vsn	Current CAP version	1.0.2.0
$secondary\_sop\_vsn$	Previous SOP version	4.12.0.240
$secondary\_cap\_vsn$	Previous CAP version	1.0.1.0

Because the upgrade application is run very early during Reader initialization, there are several restrictions on this application and what it is permitted to do. Failure to follow these restrictions could result in a failure of the Reader to initialize. These restrictions include:

- When the upgrade application is invoked, the Reader has not completed its boot sequence yet. This implies that no RFID applications are available, nor is there any network connectivity. Therefore, the application should not start the actual custom application, nor should it attempt to access the network.
- When the upgrade application is invoked after an upgrade, <old\_cust\_dir> is mounted temporarily and is read-only. This means that all access to this mount point must occur within the upgrade application. The mount point is no longer available after the upgrade application terminates.
- Because the upgrade application is called prior to the run-time Reader applications, it must ensure prompt execution so that Reader initialization can proceed. Lengthy execution times for the upgrade application (several minutes) could result in a Reader reset. If the situation persists, a fallback to the secondary image might be required.

Figure 3.3 shows an example of an upgrade application in the form of a Bash shell script.

```
#!/bin/sh
event=$1
echo "Customer application upgrade script enters"
echo "Primary SOP version is $primary_sop_vsn"
echo "Primary CAP version is $primary_cap_vsn"
test! -z $secondary_sop_vsn &&
echo "Secondary_sop_vsn &&
echo "Secondary_cap_vsn &&
echo "Secondary_cap_vsn &&
if [ $event = "cdr" ] ; then
echo "Reader has restored its default configuration"
```

```
# Copy default to current configuration
if [ -f /cust/config/default_config ] ; then
    cp /cust/config/default_config /cust/config/my_config
fi
elif [ $event = "upg" ] ; then
    echo "Reader has been upgraded"
    cust_dir=$2
    old_cust_dir=$3
    # Copy previous to current configuration
    if [ -f $old_cust_dir/config/my_config ] ; then
        cp $old_cust_dir/config/my_config $cust_dir/config/my_config
    fi
```

Figure 3.3 Example Customer Upgrade Application

## 3.2.2 Run-Time Applications

After the appropriate image partitions have been mounted and any upgrade operations have completed, the run-time Reader applications are started. This includes applications related to network management, logging, upgrade, watchdog, and of course, RFID. Applications are started using standard Linux boot procedures and therefore should not assume a boot order.

As the run-time applications are being started, any custom applications that are present on the Reader are also started. Custom applications are started like any other run-time application and therefore must adhere to the same restrictions. These restrictions include:

- No boot order may be assumed. Custom applications must be robust enough to handle scenarios in which required resources are not yet available. Figure 3.4 shows how an application's start script can wait for network availability before calling the application.
- Applications are launched as daemons, and should behave as such. Custom monitoring of application health can be implemented.

For more information about starting custom applications, see section 4.2.1 and section 4.2.2.

```
#!/bin/sh

# Wait until the network is both connected and we have a DNS server
while true; do
netconf | grep -q "connectionStatus='Connected"' && dnsconf | grep -q Server && break
sleep 1
done

# Network is now up!

# Now start custom application ...
```

Figure 3.4 Delaying Custom Application for Network

# 4 Software Development Process

This section provides information about embedded developer resources and procedures from the Speedway Revolution SDK. This information enables a developer to write an example application, generate the appropriate binaries, install the example application on the Reader, and execute the application.

## 4.1 Tools

The Speedway Revolution Reader uses a Linux kernel from the 'Squeeze' release of the Debian distribution. The Linux kernel version is 2.6.39.4. See https://www.debian.org/releases/squeeze for more information.

An embedded software developer can develop a custom application by using the Octane Embedded Development Tools available from the Impinj Support Portal. This package includes the Impinj LLRP libraries for C and C++, a sample application, a cross-compiled toolchain, and other utilities.

Note that the Embedded Developers Kit (EDK) that is based on the Linux Virtual Machine (VM) is no longer supported, and therefore is not recommended for developing new applications.

# 4.2 Accessing the Linux Shell

The Speedway Revolution Reader has its own CLI named RFID-Shell, or RShell. End users can access this interface by using the RS-232 console port, or by connecting to the Reader over the network via SSH or Telnet if it is configured. For more information, see section 4.3.2.

Using this interface, you can configure the Reader and display system information. However, for an embedded developer, this interface is insufficient and access to the underlying Linux shell is required. Because of the critical nature of this interface and the ability to adversely affect Reader behavior if it is misused, access to the Linux shell (named OSShell) is protected from the end user.

For an embedded developer, access to this interface is made possible via a custom application configuration file that is built into the CAP upgrade image. For details about creating the CAP partition, please refer to the instructions provided with the Embedded Development Tools from the Impini Support Portal.

To enable access to OSShell via RShell, You must create the following file within the CAP file system, for example:

/cust/sys/reader.conf

This file does much more than just enable access to OSShell. More specific information is provided in section 4.3.

For OSShell access, the following lines (or *stanza*) must appear within the file.

```
[rshell]
password=developer
```

## Figure 4.1 Enabling Access to OSShell

After you build an upgrade image with the CAP partition containing this file, and the upgrade image is loaded onto the Reader, you can enable access to OSShell by using the following RShell command:

```
> osshell developer
```

The password **developer** in this example must match the password that exists in the Reader configuration file loaded on to the Reader. Invalid passwords will be rejected as if the command was invalid for security purposes. The OSShell feature is intended for embedded developers only. If the password is left blank (that is, **password=**), then password checking is disabled.

Note: Impinj highly recommends that the OSShell feature be disabled in deployed CAP image files.

## File Transfer Protocol (FTP)

There is an FTP server on the Reader that can be used to transfer files to the Reader. As a security measure, this service is disabled by default. To use the FTP server on the Reader, the service must be enabled using the Reader configuration file. For information about how to enable FTP, see section 4.4.5.

Note: Similar to the OSShell password, Impinj does not recommend deploying Readers with this feature enabled.

## 4.2.1 Executing the Custom Application

Now that the custom application has been loaded on to the Reader, it can be tested. Connect to the Reader via SSH and attach a serial cable to the DE15 connector on the Reader. The procedure is illustrated here by using **CustApp**, a hypothetical example that accepts some input, prints a message, and exits.

#### To test the custom application CustApp

1. Log on to the Reader as the root user.

- 2. Access OSShell:
  - > osshell developer
- 3. Navigate to the directory where the custom application binary was stored. If this was a development build and the file was transferred via NFS or FTP, go to the directory where the binary was transferred. If this is a deployed image, navigate to the CAP.

```
# cd /cust
```

4. Run the custom application from the command line. Note that when the application runs in the foreground, the command prompt will hang up.

```
# ./CustApp
```

- 5. Now enter several characters in the terminal program. If everything is working correctly, those characters should now appear in both the terminal window and the SSH window where the application is running. When you type a customized character (A in the example code), the result should be that the customized string appears in the SSH window. Figure 4.2 is a sample output from the SSH window.
- 6. Press **ESC** to quit the program.

```
root@SpeedwayR-00-00-00:/cust#
root@SpeedwayR-00-00-00:/cust#./CustApp
abcdefghijklmnopqrstuvwxyz0123456789
Hello Friends!
The End!
root@SpeedwayR-00-00-00:/cust#
```

Figure 4.2 Sample Example Application Output

## 4.2.2 Automatically Starting a Custom Application

The custom application in this example is one that is intended to be run manually, and is for demonstration purposes only. A typical custom application would be started along with the other run-time Reader applications, as described in section 3.2.2.

To configure a custom application to be started when the Reader is reset, the Linux boot process invokes the following application at system startup:

/cust/start

This application is provided by the embedded developer and must have executable permissions. This application is started only once in the background, and its responsibility is to launch the custom application(s) as required. Of course, this may itself be the custom application, or it could be a shell script that launches, and perhaps monitors, other applications.

Figure 4.3 is an example of this type of script. This example tests for the presence of a custom application, and, if it is executable, starts it. If the application ends, it logs a message and re-starts the application, after a delay to prevent spinning.

```
#!/bin/sh
export LD LIBRARY PATH=/cust/lib
((\text{count} = 1))
while true; do
  if [-f/cust/app/rfid_control]; then
    if [-x /cust/app/rfid control]; then
      /cust/app/rfid control
      /usr/bin/logger -p user.notice \
      "Restarting custom application, count $count."
      ((count = count + 1))
    fi
    sleep 10
  else
    exit 0
  fi
done
```

Figure 4.3 Example Customer Start Application

## 4.2.3 Custom Application Library Dependencies

The Speedway Revolution firmware contains a minimal set of libraries that are required for the applications which it supports. It is conceivable that a custom application could require additional libraries to operate that are not included in the SOP. Embedded applications that require additional library support can include these libraries in their CAP image, and can configure Linux via the LD\_LIBRARY\_PATH environment variable to scan the CAP partition when it searches for dynamic library dependencies.

A typical example of this might be if a custom application is written in C++ and requires the dynamic library libstdc++, which is not included in the SOP. To handle this scenario, developers should include this library in their CAP file system. Then the custom application start script should set the LD\_LIBRARY\_PATH environment variable to point to the appropriate directory where the shared objects are located, as is shown in the sample start script in Figure 4.3.

## 4.3 Firmware Upgrade Procedure

Speedway Revolution provides three methods for managing the firmware image: upgrade to a new image, fallback to a previous valid image, and default restore. Upgrades can be accomplished without disturbing the current Reader operation, and do not take effect until the Reader is rebooted, which could be automatic. This section describes the upgrade process.

## 4.3.1 Image Versioning Scheme

Each flash partition shown in Figure 2.9 has a version number associated with it. The length of the version number is 32 bits and the Reader internally maintains it as an unsigned integer. The version number is represented as a string consisting of four fields separated by "." as shown in the example below.

Example: ddd.ddd.ddd.ddd

Each field is a decimal number ranging from 0 to 255. The left-most field maps to the most significant byte of the internal **uint32\_t** version number.

For the purpose of upgrades, when two version numbers are compared, a larger integer number is considered a higher version and is therefore a newer image. There is no other meaning to the version string. The custom application can use any versioning scheme as long as the version is 32 bits long, is represented in the format shown above, and has a larger number to indicate a newer version.

## 4.3.2 RShell Upgrade Methods

Speedway Revolution provides two methods to upgrade the firmware: **manual** and **automatic**. Use manual mode to perform a one-time upgrade of an individual Reader. The manual upgrade is started by entering commands at the RShell interface. For the purposes of embedded software development, the manual method is the most useful.

You can use the automatic method to upgrade a large network of Readers automatically by managing an upgrade configuration file called a **metafile**. The automatic method is outside the scope

of this document. If you want to use the automatic method, see the *Firmware Upgrade Reference Manual* for more information.

Table 4.1 documents the various manual upgrade commands that are available via the RShell interface. This table is only intended to be a summary. For complete documentation of all available image management commands, see the RShell Reference Manual.

Table 4.1 RShell Upgrade Command Summary

RShell		
Command	Description	Auto-Reset
config image upgrade	Invoke an immediate upgrade. The image at the provided URI is downloaded to the Reader and installed over the secondary image.	No, manual reset required
config image default	Perform a configuration default restore. See Table 3.1 for complete information.	Yes
config image fallback	Fallback to the secondary image.	Yes
config image removecap	Completely remove the CAP partition. The CAP is not mounted after the reset.	Yes
show image summary	Query the status of an upgrade and display both the primary and secondary image version information (SOP, SPP, and CAP)	N/A

## 4.3.3 OSShell Upgrade Methods

In addition to the commands available to end users via RShell, there are commands available to embedded developers only via OSShell. These commands are intended to directly manipulate the CAP partition, without the need to perform an upgrade. All of these commands, if given valid data, will return a status of Command-Being-Processed and will result in an automatic Reader reset when completed. Table 4.2 provides a list of OSShell upgrade commands.

Table 4.2 OSShell Upgrade Command Summary

OSShell Command	Description	Auto- Reset
uaconf formatcap= <ver></ver>	Format the CAP partition. The <ver> field must be a valid 4-digit dotted version number (see section 4.4.1).  The CAP will be mounted after the reset with the new version, but will be empty.</ver>	Yes
uaconf removecap=true	Completely remove the CAP partition. The CAP will not be mounted after the reset.	
		Yes

It should be noted that these commands manipulate the secondary image to achieve their purpose. Therefore, when a CAP is formatted or removed, the actions occur on the secondary images. After the Reader is reset, **mounter** performs the appropriate partition copy procedures, as described in section 3.2.1. This is significant, because performing these operations means that the fallback image is no longer available after they are completed.

# 4.4 Reader Configuration

Speedway Revolution is designed to allow custom applications to control many of the features and services available to the Reader. This customization is achieved by using the /cust/sys/reader.conf configuration file that we first visited when discussing OSShell access in section 4.3. This section documents the other capabilities of this file.

## 4.4.1 Configuration File Format

The Reader configuration file /cust/sys/reader.conf is logically organized into *stanzas*. A stanza is defined as a section of the file that starts with a stanza name enclosed in brackets, and ends with either the end of the file, or the next stanza name. The opening bracket ([) of the stanza name must appear as the first character in the line, followed immediately by the stanza name, then immediately closed with a terminating bracket (]). Characters beyond the closing bracket of a stanza name are ignored.

Inside a stanza is a set of name value pairs (NVPs) in the form:

name=value

When parsing the NVPs included in a stanza, whitespace is ignored and therefore lines can be indented for clarity. The name portion of the NVP is case-sensitive, so it must appear exactly as documented to work correctly.

Table 4.3 lists the available stanzas and gives a brief summary of what each configures. As customizable services are added to the Speedway Revolution firmware, additional stanzas may be added in the future.

Table 4.3 Configuration Stanzas

Stanza Name	Description
[rshell]	Configuration of the OSShell access password.
[HardwareEvents]	Configuration of callback notifications to CAP applications based on
	certain hardware events.
[PartnerFeatures]	Configuration of specific Reader features only available to select Impinj
	partners.
[SoftwareFeatures]	Configuration of network services and other software features.

#### 4.4.2 Hardware Events

Speedway Revolution Readers have both a USB device and USB host port. When the Reader detects that a device was inserted into one of the USB ports, the Octane firmware can notify custom applications of the event. Each notification type has different characteristics, which are described in Table 4.4 and the sections that follow.

Table 4.4 Hardware Event Notification Types

Hardware Event	Port	NVP Name	NVP Value
Mass Storage Device	Host	On Mass Storage Event	Callback Script

## Mass Storage Device

This event is delivered to the custom application via a callback script. The script provided in the configuration file must be present in the file system with executable permissions. When the insertion or removal of a mass storage device is detected by the USB host port, the script is invoked, with specific command line arguments and environment variables that convey what event has occurred. The callback script can then take whatever action is required, such as transfer configuration files, transfer log files, etc. Table 4.5 lists the arguments and environment variables made available to the callback script.

## Table 4.5 Mass Storage Event Variables

Variable Name	Description
Command Line Argument 1	Event Type: <add remove=""  =""></add>
Command Line Argument 2	File System Path
Environment ACTION	Event Type: <add remove=""  =""></add>
Environment MDEV	Device Name: e.g. <sda1></sda1>

Note that when a mass storage device insertion has been detected, the callback script does not need to mount the device. The Revolution firmware will already have mounted the device by the time the callback script is invoked and will pass that path via the second command line argument (e.g. /mnt/usbfs/usbsda1/).

## 4.4.3 Partner Features

Some Speedway Revolution features were developed for specific Impinj partners, and must be explicitly enabled before they will operate. This section of the Reader configuration file is used to enable these features. The details of how this is performed are outside the scope of this document. For information about specific features and how they are enabled, please contact your Impinj Sales Representative.

## 4.4.4 Software Features

Speedway Revolution firmware supports a number of commonly used network services. However, by default, only a subset of those services is enabled for security purposes. Embedded developers can customize those services by using the Reader configuration file.

Table 4.6 lists the available network services on the Reader, and whether they can be customized. The NVP name is the case-sensitive line that must appear within the SoftwareFeatures stanza of the Reader configuration file in order to customize the service.

Table 4.6 Customizable Network Services

Service	Default	NVP Name
DNS-SD (HTTP)	On	StartDnsSDHttp
DNS-SD (LLRP)	On	StartDnsSDLlrp
LLA	On	StartLLA
mDNS	On	StartmDNS
NTP	On	StartNTP
SNMP	On	DefaultStartSnmp
FTP	Off	StartFTP
Telnet	Off	StartTelnet

Service	Default	NVP Name
HTTP	On	StartHTTP
FTP Upgrade	On	AllowUpgradeFTP
HTTP Upgrade	On	AllowUpgradeHTTP
Web Upgrade	On	${ m Allow Upgrade Web}$
TFTP Upgrade	On	${\bf Allow Upgrade TFTP}$

## 4.4.5 Configuration File Example

Figure 4.4 depicts a sample Reader configuration file. This is provided as an illustrative example for embedded developers to better understand the file format and its contents.

```
#
# This is a sample reader configuration file.
# Note that lines beginning with a # are ignored.
#
[rshell]
  # This is the OSShell password. It should be something more secure
  # than this example, and should be disabled after it is deployed.
  password=developer
[HardwareEvents]
  # Invoke special script on a mass-storage device
  OnMassStorageEvent=/cust/bin/sdAction.sh
[PartnerFeatures]
  # Enable an example reader feature here
[SoftwareFeatures]
  # Turn on telnet for security purposes
  StartTelnet=yes
  # Turn on FTP for development (TODO: turn off)
  StartFTP=yes
  # Turn off NTP and rely on the RTC for time
  StartNTP=no
  # Do not advertise any reader services
  StartDnsSDHttp=no
  StartDnsSDLlrp=no
```

# 5 Document Revision History

Date	Revision	Comments
04/08/2009	4.0	Original Release
08/27/2009	4.2	Updated for Octane Release 4.2
03/31/2010	4.4	Updated for Octane Release 4.4
06/02/2010	4.4.1	Moved description of tools to EDK web pages
12/14/2010	4.6.1	Updates for release of $4.6$ and EDK $1.0$
04/25/2011	4.8.0	Updates for Octane 4.8 release
02/13/2012	4.10.0	Added comment on unused serial pins on RJ45. Updated for Octane 4.10 release 2.1.4 The remaining pins are not utilized by the Reader and are left unconnected.
12/16/2014	5.2.0	Added information about xPortal and xArray Gateway products Added information about Speedway Revolution H/W changes (PCBA v5.xx an up) Refer to the Embedded Development Tools from Portal instead of EDK Updated versions for Octane 5.2 release. Edited, updated cross references, and made figure and table names consistent.
